linux-libre 5.12.6 instability

2021-06-07 07:04 AM - CBotulinum

Status:	unconfirmed	% Done:	0%
Priority:	bug		
Assignee:	Megver83		
Category:			
Description			
<ul style="list-style-type: none">steps to reproduce: On an Intel C2D system (Librebooted ThinkPad T400), using this kernel version is rather unstable (linux-libre 5.12.6).expected result: Stable-running system as usual, with suspend to RAM working.actual result: Suspend to RAM is broken (the system just hangs while attempting to suspend), doesn't even respond to Magic SysRq. In addition, the system crashes after a while of being booted up. Note that none of the aforementioned issues happen on the LTS kernel (linux-libre-lts 5.10.39). I've checked through the logs, but nothing appears before or after the crash that could indicate as to why it happened.

Upstream (Arch) seems to have conflicting reports on the same issues, with some users stating that 5.12.7 solves this problem for them:
